

Alla Vostra Mobile App Work Log - September 17, 2026

Compiled summary for Thursday, September 17, 2026 - focus: verified U.S. Eastern-time date handling, full pre-existing worklog review, Google Pay production approval, Android 1.0.4 Play-signed installation, private internal-track delivery, live Google Pay and Stripe decline verification, production-release promotion and review submission, iPhone 17e and iPhone 17 Pro Max simulator setup, physical iPhone 14 testing, synchronized three-device visual checkout QA, unfinished iOS backend isolation, reusable cross-project XCTest harness preservation, project snapshot refresh, source-control clarification, and current documentation artifact generation for Alla Vostra.

Generated in continuity with the established Alla Vostra worklog cadence: compact opening summary, source-material review, baseline, goals, grouped work-completed sections, validation, files and artifacts touched, external account/device context, follow-up context, and output-artifact close.

This artifact is named `alla_vostra_worklog_september17.pdf` because the user requested the current worklog while the verified U.S. Eastern-time date was Thursday, September 17, 2026. The date was checked locally with TZ=America/New_York date at 11:58:22 PM EDT and independently against UTC-04:00 at 11:58:25 PM. The Eastern calendar crossed midnight while the complete archive was being studied and the PDF was being prepared, but the artifact retained the verified request/session date rather than silently moving the work window to September 18.

This PDF records the work window after `alla_vostra_worklog_september15.pdf` and documentation commit 8a73b2b, through the September 17 Google Pay, Google Play, Android, iOS, Stripe, simulator, physical-device, visual-QA, reusable-tooling, and snapshot operations, ending at commit 4e58160 Refreshed project snapshots for checkout, payment, and release updates. The app-source, backend-source, and Android release bundle were not modified during the synchronized iOS QA work.

Source Material Reviewed

- Reviewed all 66 pre-existing root-level Alla Vostra PDF worklogs from May, June, July, August, and September to preserve the established naming pattern, title cadence, letter-size layout, section order, implementation detail, validation language, files-touched inventory, device and account context, follow-up cadence, and output-artifact close.
- Extracted every existing worklog with `pdftotext` and inspected the set with `pdftinfo`. The review covered 66 text artifacts and 149,582 extracted words before this September 17 record was drafted.
- Used `alla_vostra_worklog_september15.pdf` as the immediate continuity anchor because it documented Google Pay Console submission, Android 1.0.4 release preparation, payment hardening, native Google Pay UI, Vercel, Stripe, Postmark, and the exact follow-up state inherited by this session.
- Rechecked `alla_vostra_worklog_september12_part1.pdf` and `alla_vostra_worklog_september11.pdf` as the cleaner visual style anchors because they use the established proportional Helvetica treatment, readable bullet indentation, letter-size pages, and footer format.
- Rechecked the September 7, September 8, and September 9 worklogs for the physical iPhone, Xcode, native development-client, simulator, Expo/Metro, and device-trust context that preceded the current iOS testing matrix.
- Reviewed the project snapshots, current Git history, branch state, recent commit metadata, Google Pay and Play Console screenshots supplied during the session, Stripe dashboard evidence, disposable XCTest logs, final simulator screenshots, and the preserved reusable visual-QA harness.
- Confirmed that the immediately preceding documentation endpoint was commit 8a73b2b, followed by the September 17 snapshot-only commit 4e58160 after `read_project.sh` regenerated the tracked app and web snapshots.

Baseline Status Before September 17

- Android app version 1.0.4, version code 5, and package `com.allavostra.app` had already been prepared for Google Play, with a production AAB available and native Google Pay integrated through Stripe.
- Google Pay business-profile work and the Android integration submission had been completed on September 15, but the integration was still awaiting Google review and could not yet be treated as production-approved.
- The available Android 1.0.4 APK was suitable for installation and preview testing, but a sideloaded APK could be signed with the EAS upload key rather than Google Play's app-signing key.
- The live backend, Stripe webhook, order validation, fulfillment metadata, merchant notification, CORS, and rate-limiting work had already been committed, tested, and deployed during the prior release-preparation window.
- The iOS interface was considered visually finished for the planned work, while its backend path was explicitly still unfinished. The user wanted to make small iOS changes later without disturbing the Android submission.

- Physical iOS coverage was limited to an iPhone 14, so wide/tall simulator coverage was needed to inspect the same flow on current larger and compact device classes.
- No reusable project-independent command yet existed for launching synchronized visual UI tests across multiple simulators and a physical iPhone.

Goals for September 17

- Confirm Google Pay production approval and validate the Android integration state in Google Pay & Wallet Console.
- Test Android 1.0.4 with a Google Play-signed installation rather than relying on a sideloaded APK whose signing identity could cause Google Pay production rejection.
- Use Google Play internal testing only as a private delivery mechanism, without repeating the historical 12-testers/14-days qualification process for an already-published app.
- Verify that the live Google Pay flow reaches Stripe and the card issuer while avoiding any false claim that a failed or declined payment completed successfully.
- Promote the exact tested version 5 bundle to production while reviewing Play Console warnings and leaving the release in Google's normal review path.
- Establish iPhone 17e, iPhone 17 Pro Max, and physical iPhone 14 coverage while preserving backend compatibility and keeping the Android Play submission unchanged.
- Demonstrate the complete shopping flow visibly and synchronously on all three iOS devices, holding each major state long enough for human observation.
- Preserve the resulting multi-device automation as reusable tooling outside the Alla Vostra production repository.

Work Completed - Google Pay Approval and Android Verification

- Reviewed the Google Payment API support email confirming that the submitted Google Pay integration had been approved and that an official confirmation was sent to the registered address.
- Confirmed in Google Pay & Wallet Console that com.allavostra.app appeared Active under Android and Web integration.
- Used the Galaxy S20 Ultra as the applicable physical Android verification device and confirmed that version 1.0.4 was installed after the older 1.0.3 installation was identified.
- Enabled USB debugging through Android Developer options and authorized the connected Mac so ADB-level package and screen checks could be performed.
- Captured the Android failure state reading Payment not completed and Error while processing result from Google Pay.
- Identified that the installed 1.0.4 package had been installed through Android Package Installer, indicating a sideloaded build rather than the Google Play-distributed signature path.
- Treated app signing as the likely difference because Google Play re-signs uploaded app bundles with the official app-signing key used for production identity checks.

Work Completed - Internal Track and Play-Signed Installation

- Opened Google Play Console and navigated to Test and release, Testing, and Internal testing for the already-published Alla Vostra app.
- Clarified that internal testing was being used only to deliver a Play-signed build privately; it did not restart or require the 12-testers/14-days process.
- Uploaded alla-vostra-production-1.0.4-build-5.aab to a new internal release and confirmed that Play processed version code 5, version 1.0.4, without upload errors.
- Published the internal release so version 5 became available to internal testers.
- Inspected the tester list and found the prior testers-community@googlegroups.com entry. The user's direct Google account was added so the old community group was not required to participate in this verification.
- Copied and opened the Play opt-in link, joined the internal test with the account used on the S20 Ultra, and installed the resulting Google Play update.
- Preserved the distinction between private Play delivery and public production publication throughout the test.

Work Completed - Live Google Pay and Stripe Result Verification

- Walked the Play-signed Android build through product selection, cart, contact details, delivery schedule, address, payment method selection, confirmation, and the native Google Pay sheet.

- Reached the Pay Now state with a real Google Wallet card rather than Stripe's 4242 test card because the approved production path was operating against live payment infrastructure.
- Received the card-level result Payment not completed. Your card has insufficient funds.
- Explained that Google did not require a successful real purchase merely to prove that the production Google Pay integration could open and reach the payment processor.
- Opened the live Alla Vostra Stripe account rather than the Sandbox account and inspected Transactions.
- Confirmed the latest \$69.55 attempt appeared as Failed, used Google Pay with Visa ending 5195, and carried the expected Alla Vostra order/customer context.
- Confirmed there was no separate successful \$69.55 charge, so the test created no completed order or captured payment.
- Interpreted the issuer decline as evidence that the Play-signed production integration passed Google Pay tokenization and reached Stripe/card authorization; the remaining failure was insufficient card funds, not the earlier generic Google Pay result-processing error.

Work Completed - Production Release Promotion

- Returned to the Google Play internal-testing release and promoted the exact version 5 (1.0.4) bundle to Production rather than rebuilding or uploading a different artifact.
- Reviewed Play Console's supported-device change report before continuing.
- Confirmed that no phones were removed. The 26 newly unsupported devices consisted of six tablets, three TVs, and seventeen cars, all outside the intended phone-focused Alla Vostra experience.
- Reviewed the missing deobfuscation-file warning and accepted it because R8/ProGuard minification was disabled for this build, so no mapping file was generated or required for decoding obfuscated stack traces.
- Created the full production rollout, saved it to Publishing overview, and submitted the single production change for Google review.
- Confirmed the resulting Publishing overview showed Changes in review for Production 5 (1.0.4), Start full rollout.
- Noted that Managed publishing was off, meaning Google Play would publish the approved release automatically after review rather than waiting for a separate manual publish action.

Work Completed - iOS Device Matrix and Backend Guardrails

- Clarified the iOS scope after the user corrected that the iOS UI was finished but the backend was not.
- Recommended continuing iOS backend work on a separate branch and staging environment so unfinished work would not interfere with the submitted Android release.
- Preserved five explicit implementation guardrails: backward-compatible Android API behavior, additive database migrations, completed iOS flow testing through TestFlight against staging, production deployment of only backward-compatible backend changes, and no changes to the Android Play submission.
- Confirmed the available simulator set and booted iPhone 17e and iPhone 17 Pro Max for compact and widest/tallest current iPhone coverage.
- Closed unrelated Cinerific processes when requested so the device and simulator session remained focused.
- Launched Alla Vostra on both simulators and then on the connected physical iPhone 14 after device trust was confirmed.
- Kept the simulator/device work local; no backend deployment, database migration, TestFlight release, or Android bundle replacement occurred.

Work Completed - Synchronized Three-Device Visual QA

- Responded to the request for a visible, simultaneous Home-to-Shop-to-product-to-checkout walkthrough with at least ten seconds on every major screen.
- Corrected the first automation attempt after it stopped at the Piccola product overlay and did not visibly demonstrate the full navigation the user expected.
- Kept all corrective work in a disposable XCTest project under /tmp rather than changing the app's scripts or source code.
- Built a complete accessibility-label-driven XCTest flow for the iPhone 17e simulator, iPhone 17 Pro Max simulator, and physical iPhone 14.
- Used a shared epoch so the three runners advanced within fractions of one another instead of running independently

at different speeds.

- Held and exercised the Home, Shop, Piccola details, added-product state, cart, contact, Date & Time, address, payment, Stripe card form, accepted-card state, order confirmation, and backend-result stages.
- Entered safe QA data, selected October 1 and 7:15 PM, used an Aventura, Florida address, and entered Stripe test card 4242 4242 4242 4242 with test expiration, CVC, and ZIP values.
- Reached Place order and Yes on all three devices. Every UI-test runner exited successfully, demonstrating that the same visible interaction path was repeatable across the compact simulator, large simulator, and physical phone.
- Observed the genuine final backend result on all three devices: Payment not completed and There was an unexpected error -- try again in a few seconds.
- Did not fake an order-success screen. No successful order or charge was claimed, and the common three-device result isolated the remaining work to the unfinished iOS backend/staging payment path rather than responsive UI navigation.

Work Completed - Reusable Visual QA Harness

- Preserved the successful orchestration as a standalone tool at /Users/prahlin/gh/visual-qa so it can support other projects without becoming part of Alla Vostra's production application repository.
- Added a shared visual-qa launcher that boots configured simulators, prepares and signs XCTest runners, discovers installed app paths, injects a synchronized start time, launches all destinations concurrently, and reports per-device pass/fail status.
- Added an Alla Vostra scenario containing the three current device destinations, bundle identifier, signing team, XCTest identifier, and full timed shopping-flow implementation.
- Added a reusable Xcode UI-test project template and a README describing prerequisites, execution, logs, new-project setup, and payment-safety boundaries.
- Configured logs to live under ~/Library/Logs/VisualQA/<scenario>/<timestamp> and temporary derived test builds under /tmp/visual-qa-<scenario>.
- Verified shell syntax, scenario discovery, Xcode project/scheme visibility, Swift compilation, and simulator build-for-testing output without rerunning the full checkout presentation.
- Kept the harness outside /Users/prahlin/gh/alla_vostra, so saving it created no additional Alla Vostra Source Control entries.

Work Completed - Snapshot Refresh and Source Control Clarification

- Ran read_project.sh as originally requested to refresh project context before continuing the session.
- Explained that read_project.sh rewrites both tracked snapshot files with a new timestamp, current file tree, and selected source contents every time it runs.
- Identified the two resulting Source Control changes as alla_vostra_APP_PROJECT_SNAPSHOT.txt and alla_vostra_WEB_PROJECT_SNAPSHOT.txt rather than changes to application implementation files.
- Explained why the snapshot diff was unusually large: numbered source lines shift after insertions, and the tree generator currently includes generated areas such as Android .gradle state and Vercel output directories.
- Preserved the refreshed snapshots instead of reverting requested documentation output without approval.
- Recorded the refresh in commit 4e58160, which captured the current checkout, payment, release, backend-test, screenshot, deployment, and September 15 documentation state.
- Confirmed main matched origin/main after the snapshot commit and before this new PDF artifact was created.

Validation and Checks Performed

- Verified September 17 independently in U.S. Eastern time before midnight using both TZ=America/New_York date and an external UTC-04:00 time check.
- Extracted and inventoried all 66 pre-existing worklog PDFs, totaling 149,582 words, and compared recent titles, section patterns, page counts, metadata, fonts, and first-page layout.
- Confirmed Google Pay & Wallet Console showed the Alla Vostra Android integration as Active for com.allavostra.app.
- Confirmed Play Console accepted version code 5, version 1.0.4 on the internal track and made it available to the configured tester account.
- Confirmed the S20 Ultra installed the Google Play-distributed 1.0.4 update and advanced into the live native Google Pay sheet.

- Confirmed Stripe live Transactions recorded the \$69.55 attempt as Failed for insufficient funds and showed no matching successful charge.
- Confirmed Play Console accepted the production promotion and showed Production 5 (1.0.4), Start full rollout under Changes in review.
- Confirmed the device-support warning removed zero phones and the deobfuscation warning did not require action for the non-minified build.
- Confirmed the iPhone 17e, iPhone 17 Pro Max, and physical iPhone 14 all completed the synchronized visible flow and reached the same backend result.
- Confirmed each automated visual stage was held for at least ten seconds and all three XCTest runner commands exited with status zero.
- Confirmed the standalone visual-QA runner compiled successfully for iOS Simulator and its generated xctestrun manifest exposed the expected VisualQARunner target.
- Confirmed no Alla Vostra app source, backend source, database schema, production environment, or Android bundle was changed by the visual-QA automation.

Files and Artifacts Touched During the September 17 Window

- `alla_vostra_APP_PROJECT_SNAPSHOT.txt` - regenerated from current mobile source and tree state by `read_project.sh`, then committed in 4e58160.
- `alla_vostra_WEB_PROJECT_SNAPSHOT.txt` - regenerated from current web/root/server tree and selected source state, then committed in 4e58160.
- `/Users/prahlin/Downloads/alla-vostra-production-1.0.4-build-5.aab` - reused as the version 5 internal and production Play bundle; it was not rebuilt during this session.
- `/Users/prahlin/gh/visual-qa/visual-qa` - added the reusable synchronized multi-device launcher outside the Alla Vostra repository.
- `/Users/prahlin/gh/visual-qa/scenarios/alla-vostra/config.sh` - stored Alla Vostra's simulator IDs, physical-device destination, bundle ID, signing team, and test selection.
- `/Users/prahlin/gh/visual-qa/scenarios/alla-vostra/ShopFlowUITests.swift` - stored the timed end-to-end shopping scenario and current expected backend-result handling.
- `/Users/prahlin/gh/visual-qa/templates/VisualQARunner.xcodeproj` - stored the reusable XCTest runner template.
- `/Users/prahlin/gh/visual-qa/README.md` - documented reuse, project onboarding, logs, prerequisites, and payment safety.
- Temporary `/tmp` XCTest projects, build products, logs, and simulator screenshots were used for the live QA run; large derived build directories were removed afterward to recover disk space.

External Account, Device, and Release Context

- Google Pay API support confirmed approval by email, and Google Pay & Wallet Console showed the registered Android integration as Active.
- Google Play Console app context remained Alla Vostra Grazing Boards, package `com.allavostra.app`.
- Internal testing contained the historical testers-community Google Group and the user's directly added tester account; the group was not required for the current private install.
- Google Play production context ended with version 5 (1.0.4) submitted for review as a full rollout with Managed publishing off.
- Android verification used the connected Galaxy S20 Ultra with USB debugging enabled and a real Google Wallet card that returned an insufficient-funds decline.
- Stripe verification used the live Alla Vostra dashboard and observed a failed \$69.55 Google Pay Visa attempt ending in 5195, with no succeeded duplicate.
- iOS visual coverage used iPhone 17e simulator 96B133B5-D949-43E6-8740-3B12E246350E, iPhone 17 Pro Max simulator 8449C0A0-A7AE-44CB-B24F-D3EE6BB0606D, and physical iPhone 14 destination 00008110-000A31300EA1401E.
- The iOS QA card data was Stripe's standard test value and did not represent a real card or real charge.
- The reusable harness remained a neighboring directory under `/Users/prahlin/gh` rather than a child of the Alla Vostra repository.

Follow-Up Context

- Google Play production version 1.0.4 remains subject to Google's review. Because Managed publishing is off, approval should transition the release automatically unless Play reports another issue.
- The Android production Google Pay path reached the issuer successfully. A future successful-payment smoke test can be performed when an appropriately funded card is available, but the insufficient-funds result was enough to distinguish the path from the prior signing/integration failure.
- The iOS UI flow is broadly repeatable across compact, large, and physical devices, but the backend payment result remains unfinished and must be addressed in staging before claiming an end-to-end iOS order success.
- Future iOS backend changes should stay on a separate branch and staging environment, keep Android API contracts backward-compatible, and use additive database migrations.
- The completed iOS flow should be tested through TestFlight against staging before compatible backend changes are promoted to production.
- The submitted Android Play bundle should remain unchanged while iOS backend work proceeds.
- Future projects can reuse /Users/prahlin/gh/visual-qa by adding a scenario config and accessibility-driven Swift flow; stable accessibility identifiers will make those scenarios less dependent on visible copy.
- The current snapshot generator could later exclude generated .gradle, Pods, and Vercel output folders to reduce noisy documentation diffs, but no generator refactor was performed in this session.
- The latest committed repository endpoint before this PDF is 4e58160, and the working tree was clean immediately before generating the worklog artifact.

Output Artifact

- Generated this worklog in the established Alla Vostra long-form mobile-app documentation style after reviewing the complete prior PDF set.
- Rendered the artifact as a U.S.-letter PDF with proportional typography, section headings, implementation-oriented hyphen bullets, and page-number footers.
- Location: repository root, alongside the existing root-level worklog PDFs.
- Generated worklog artifact: `alla_vostra_worklog_september17.pdf`.
